**Abstract**

Oxidative damage is implicated in the pathogenesis of various liver injuries. The study was aimed to investigate the antioxidant activity of *Coriandrum sativum* on CCl_4 treated oxidative stress in Wistar albino rats. CCl_4 injection induced oxidative stress by a significant rise in serum marker enzymes and thiobarbituric acid reactive substances (TBARS) along with the reduction of antioxidant enzymes. In serum, the activities of enzymes like ALP, ACP and protein and bilirubin were evaluated. Pretreatment of rats with different doses of plant extract (100 and 200 mg/kg) significantly reduced the toxic effects of CCl_4. The activity of leaf extract at a dose of 200 mg/kg body weight significantly reduced the toxic effects of CCl_4. The activity of leaf extract at the dose of 200 mg/kg was comparable to the standard drug, silymarin. Based on these results, it was observed that *C. sativum* extract protects liver from oxidative stress induced by CCl_4 and thus helps in evaluation of traditional claim on this plant.

**Keywords**: *Coriandrum sativum*, Carbon tetrachloride, Hepatotoxicity, Oxidative stress, Protective effect

**1. Introduction**

Liver is the first organ to metabolize all foreign compounds and hence it is susceptible to almost as many different diseases. Some are rare but there are a few, including hepatitis, cirrhosis, alcohol-related disorders and liver cancer. A major cause of these disorders is due to exposure to different environmental pollutants and xenobiotics e.g., paracetamol, carbon tetrachloride, thioacetamide, alcohol, etc. These toxicants mainly damage liver by producing reactive oxygen species (ROS).

Reactive oxygen free radicals have been known to produce tissue injury through covalent binding and lipid peroxidation and have been shown to augment fibrosis as seen from increased collagen synthesis (Geesin et al., 1990). Scavenging of free radicals by antioxidants could reduce the fibrosis process in the tissues (Thre差ma and Kuttan, 1996). Free radicals may also be a contributory factor in a progressive decline in the function of immune system (Pike and Chandra, 1995). Cooperative defense systems that protect the body from free radical damage include the antioxidant nutrients and enzymes. The antioxidant enzymes include superoxide dismutase (SOD), catalase (CAT) and glutathione peroxidase (GPx). Their role as protective enzymes is well-known and has been investigated extensively with in vivo models.

Conventional or synthetic drugs used in the treatment of liver diseases are inadequate and can have serious adverse effects. So there is a worldwide trend to go back to traditional medicinal plants. Many natural products of herbal origin are in use for the treatment of liver ailments. Polyphenolic compounds are widely distributed in plants and known to be excellent antioxidants in vitro and have the capacity to scavenge free radicals and protect antioxidant defence (Venkateswaran et al., 1997; Latha et al., 1999; Mitra et al., 2000; Dhuley and Naik, 1997).

Several medicinal plants have been screened based on the integrative approaches on drug development from Ayurveda (Mukherjee and Wahile, 2006). Since dietary polyphenol has been reported to be inversely associated with lipid peroxidation and cytotoxicity, an attempt was made to study the effects of the extracts of *Coriandrum sativum* on the activities of antioxidant enzymes in CCl_4 treated liver. *C. sativum* also called as “cilantro” is a well-known plant derived from the traditional system of medicine in India and a native of Mediterranean region. There are two distinct species with distinct morphological types. Only *C. sativum* L. is cultivated widely in the tropics. India has the prime position in the cultivation and production of Coriander (Sharma and Sharma, 2004). The seeds contain an essential oil “linalool" a monoterpenoid and the leaves contain good amount of caffeic acid, ferulic...
acids, gallic acid and chlorogenic acid (Bajpai et al., 2005). The seeds and aerial parts of the plant are extensively used in traditional systems of medicine for various ailments like spasm (Kurian, 2003), rheumatism, neuralgia, gastric complaints (Khare, 2004) bronchitis, diarrhoea, dysentery, gout, dyspepsia and giddiness. The plant is known to possess hypoglycemic (Chithra and Leelamma, 2000) antibacterial, antifungal (Fujita, 2004) free radical scavenging and lipid peroxidation activities (Tanabe et al., 2002). *C. sativum* was used as herbal constituent in the polyherbal formulation LIV-O-G which has been claimed to improve the liver dysfunction (Naidu et al., 2007). Quercetin 3-glucuronide, isoorciquitin and rutin were separated and identified in coriander fruits by means of chromatography on cellulose columns (Kunzemann & Herrmann, 1977). But no detailed investigations were carried out on the antioxidiant effect of coriander leaf extracts. Since coriander leaves are one of the commonly used spices, we have made an attempt to evaluate the hepatoprotective effect of the leaves on oxidative damage induced by CCl₄ in rat hepatocytes.

### 2. Materials and methods

#### 2.1. Plant material

The fresh leaves and stem of *C. sativum* were collected from the Horticultural research institute, Coimbatore, Tamilnadu region, India and authenticated through Botanical survey of India, Coimbatore, Tamilnadu, India. A voucher specimen has been deposited at the Herbarium unit. The plant samples were air-dried for 10 days and powdered. The powdered samples were placed in air tight container for future use.

#### 2.2. Extraction

The air-dried leaves of *C. sativum* were made into a coarse powder. Two hundred and fifty grams of the powder was extracted with mixture of ethanol: water (5:1) as solvent system and visualised using vanillin sulphuric acid reagent. The Linomat IV Automatic spotter. TLC pattern was developed using toluene:acetone (19:81) as solvent system and visualised using vanillin sulphuric acid reagent. Twenty microliters of the extract was spotted in the form of a band using linomat IV Automatic spotter. TLC pattern was developed using toluene:acetone (19:81) as solvent system and visualised using vanillin sulphuric acid reagent. Twenty microliters of the extract was spotted in the form of a band using Linomat IV Automatic spotter. The reaction mixture consisted of 400 μM H₂O₂ and catalase (CAT) and superoxide dismutase (SOD) and glutathione peroxidase (GPX). Total protein contents were determined by the method of Lowry et al. (1951), using bovine serum albumin as a standard. Activities of glutamate oxaloacetate transaminase (GOT), glutamate pyruvate transaminase (GPT), alkaline phosphatase (ALP) and acid phosphatase (ACP) were determined using commercial kit.

#### 2.3. Animals

Wistar albino rats (180–230 g) of either sex, procured from Tamilnadu University of Veterinary and Animal Sciences (TANUVAS) were used for the study. The animals were housed in large polypropylene cages in a temperature-controlled room (22 ± 2 °C) and provided with standardized pelleted feed (TANUVAS) and clean drinking water ad libitum. The study has got the clearance from the Institutional Animal Ethical Committee (IAEC) the Committee for the Purpose of Control and Supervision of Experiments on Animals (CPCSEA).

#### 2.4. Phytochemical analysis

The leaves were subjected to preliminary phytochemical screening to identify the presence of various phytoconstituents present in the extract (Kokate et al., 1997) Precoated TLC plate of silicagel 60F254 (E. Merck, India) of 0.2 mm thickness was used. Twenty microliters of the extract was spotted in the form of a band using Linomat IV Automatic spotter. TLC pattern was developed using toluene:acetone (5:1) as solvent system and visualised using vanillin sulphuric acid reagent. The r.f values and the percentage of separated compounds were determined.

#### 2.5. Behavioural and toxic effects

Different groups of mice were treated with graded doses of the *C. sativum* extract (100 mg, 200 mg, 500 mg and 750 mg/kg, p.o.). One group was maintained as control and was given 0.5% Tween-80. They were observed continuously for 1 h for any gross behavioural changes and death, if any and then, intermittently for the next 6h, and then again at 24 h after dosing with *C. sativum* extract.

#### 2.6. Experimental procedure

Carbon tetrachloride (CCl₄) is a powerful hepatotoxin which is used extensively to generate experiments to study necrosis and steatosis of the liver in the rat (Perez-Tamayo, 1983; Wensing et al., 1990). Albino rats 4–6 weeks, 180–230 g were divided in to six groups of six animals each. CCl₄ (1 ml/kg body weight) was administered to all groups of animals by intraperitoneal injection which is well documented to induce acute hepatic toxicity in rats (Wong et al., 2003). Group I served as control group, receiving normal saline only (10 ml/kg p.i.). Group II served as CCl₄ control and received CCl₄:olive oil (1:1) on the 15th day. Group III and Group IV received the C. sativum stem extract that were given in two divided doses 100 mg/kg and 200 mg/kg respectively, Group V and Group VI received the C. sativum leaf extract that were given in two divided doses 100 mg/kg and 200 mg/kg, respectively, and the reference drug silymarin (25 ml/kg i.p.) was administered to Group VII, respectively, daily once for 15 days after CCl₄ administration. All the animals were killed at the end of 15th day after CCl₄ administration, blood was drawn from the carotid artery and serum was separated for the different assays.

#### 2.7. Preparation of serum from blood

After 24 h, animals were sacrificed at the end of 15th day after CCl₄ administration, by chloroform anaesthesia. Blood was drawn from the carotid artery and serum was separated. Serum was separated by centrifugation at 600g for 15 min and analyzed for various biochemical parameters. The sera were stored in the –80 °C freezer before they were analyzed. Enzyme activities of aspartate aminotransferase (AST) and alanine aminotransferase (ALT) in blood serum were evaluated by an automatic analyzer (Shimadzu CL-7200, Shimadzu, Japan). After bleeding, complete postmortem examinations were performed on all terminated rats. The absolute and relative (organ-to-body weight ratio) weights of the liver were also measured for all rats when they were sacrificed.

#### 2.8. Preparation of liver homogenate

Hepatic tissues were homogenized in KCl (10 mM) phosphate buffer (1.15%) with ethylene-diamine tetra-acetic acid (EDTA: pH 7.4) and centrifuged at 12,000g for 60 min. The supernatant was used for the measurement of malondialdehyde (MDA), catalase (CAT), superoxide dismutase (SOD), and glutathione peroxidase (GPX). Total protein contents were determined by the method of Lowry et al. (1951), using bovine serum albumin as a standard. Activities of glutamate oxaloacetate transaminase (GOT), glutamate pyruvate transaminase (GPT), alkaline phosphatase (ALP) and acid phosphatase (ACP) were determined using commercial kit.

#### 2.9. Determination of lipid peroxidation

Lipid peroxidation was measured by the thiobarbituric acid (TBA) reaction method (Berton et al., 1998). In brief, samples were mixed with TBA reagent consisting of 0.25% thiobarbituric acid in 0.25% H₂SO₄ and 0.6% sodium hydroxide. The reaction mixtures were placed in a boiling water bath for 30 min and centrifuged at 1811g for 5 min. The absorbance of the supernatant was measured at 535 nm. MDA, a measure of lipid peroxidation, was calculated using an extinction coefficient of 1.56 × 10³ M⁻¹ cm⁻¹. The results were expressed as μM/mg protein.

#### 2.10. Determination of antioxidant enzymes

Catalase activity was measured according to the method of Aebi (1984). One unit of catalase was defined as the amount of enzyme required to decompose 1 μM of H₂O₂ in 1 min. The reaction was initiated by the addition of 1.0 ml of freshly prepared 20 mM H₂O₂. The rate of decomposition of H₂O₂ was measured spectrophotometrically at 240 nm for 1 min. The enzyme activity was expressed as U/mg protein.

The activity of SOD was measured according to the method of McCord (1994). For the determination of SOD activity, xanthine and xanthine oxidase were used to generate superoxide radicals reacting with 2-(4-iodophenyl)-3-(4-nitropheno)-5-phenyl tetrazolium chloride to form a red formazan dye. SOD activity was then measured at 505 nm.

GPX activity was determined by the method described by Pagila and Valentine (1967) and modified by Wendel (1981). The reaction mixture consisted of 400 μL 0.25 M potassium phosphate buffer (pH 7.0), 200 μL supernatant, 100 μL GSH (10 mM), 100 μL NADPH (2.5 mM) and 100 μL glutathione reductase (6 U/mL). Reaction was started by adding 100 μL hydrogen peroxide (12 mM) and absorbance measured at 366 nm at 1 min intervals for 5 min using a molar extinction coefficient of 6.22 × 10³ M⁻¹ cm⁻¹. Data were expressed as U/mg of protein.

#### 2.11. Histopathology

After the experimental period animals were decapitated, liver removed immediately, sliced and washed in saline. Liver pieces were preserved in 10% formalin for histopathological studies. The pieces of liver were processed and embedded in paraffin wax. Sections were taken and stained with haematoxylin and eosin and photographed (Coskun et al., 2000).

#### 2.12. Statistics

All the values are represented as mean ± SE (n = 6). The statistical differences among different groups were analyzed by student’s T-test. The difference showing a p level of 0.05 or lower was considered to be statistically significant.
### 3. Results

#### 3.1. Phytochemical constituents and toxicity studies

The extract revealed the presence of various phytoconstituents like reducing and non-reducing sugars, polyphenolics, alkaloids, saponins and terpenoids. In acute toxicity, no mortality was observed up to a dose level of 750 mg/kg body weight.

#### 3.2. Effect of C. sativum on CCl₄-induced hepatotoxicity

The activities of various biochemical enzymes in normal, CCl₄ control and treated groups were represented in Tables 1 and 2. The activities of ALT, AST, ALP, ACP and total bilirubin were significantly (p < 0.001) increased with a significant decrease in total protein levels in CCl₄ control compared to normal control. The levels of the above enzymes were significantly reversed on treatment with C. sativum in a dose-dependent manner. The activity of the leaf extract at the dose of 200 mg/kg was comparable to that of the reference drug silymarin.

#### 3.3. Hepatic antioxidant enzyme activities

SOD, CAT and GPx were measured as an index of antioxidant status of tissues. Significantly lower liver SOD, catalase, and GSH-Px activity were observed in mice from the CCl₄ treated group as compared to the normal control group. There was a significant increase (p < 0.05) of SOD, CAT and GPx activity in the groups at a dose of 100 and 200 mg/kg, respectively, as compared to the CCl₄ treated group. Treatment with CCl₄ significantly decreased the SOD, CAT and GPx levels in the liver (47.84 ± 0.50, 169.73 ± 5, 0.61 ± 0.03 mg/protein) as compared to the normal control group (75.81 ± 1.94, 296.83 ± 10.05, 0.992 ± 0.05 mg/protein). By contrast, administration with C. sativum and silymarin significantly increased the levels as compared to the CCl₄-treated group. The levels were similar at animals treated with silymarin and those treated with leaf extract of C. sativum at dose of 200 mg/kg (Table 3).

#### 3.4. Lipid peroxidation

MDA level is widely used as a marker of free radical mediated lipid peroxidation injury. We measured MDA levels in the liver and the results are shown in Table 4. MDA levels in the CCl₄ treated group (2.79 ± 0.14 nmol/mg protein) were significantly higher than that in the control group (1.29 ± 0.39 nmol/mg protein, p < 0.05). MDA levels in the leaf extract treated group of C. sativum (1.46 ± 0.41 and 1.29 ± 0.4 nmol/mg protein at dose of 100 and 200 mg/kg, respectively) were significantly lower than that in the CCl₄ treated group (p < 0.05). Silymarin also inhibited the elevating MDA levels upon CCl₄ administration. These findings indicated that the free radicals being released in the liver were effectively scavenged when treated with the leaf and stem extracts of C. sativum.

fatty accumulation and necrosis. The maximum protection against hepatic damage was achieved with the leaf extract at dose of 200 mg/kg (see Fig. 1).

4. Discussion

The present study reports the potential hepatoprotective activity of *C. sativum* against hepatic injury produced by carbon-tetrachloride in rats. CCl4 is a well-known hepatotoxic agent and the preventive action of liver damage by CCl4 has been widely used as an indicator of liver protective activity of drugs in general. The changes associated with CCl4-induced liver damage are similar to that of acute viral hepatitis. It is metabolized in the liver to excretible glucuronide and sulphide conjugates (Jollow et al., 1974). An obvious sign of hepatic injury is the leaking of cellular enzymes into the plasma (Schmit et al., 1975) due to the disturbance caused in the transport function of hepatocytes (Zimmerman and Seeff, 1970). When liver call plasma is damaged a variety of enzymes located normally in cytosol is released into the blood, thereby causing increased enzyme level in the serum. The estimation of enzymes in the serum is a useful quantitative marker of the extent and types of hepatic cellular damage (Jadon et al., 2007).

In the present investigation, the dose of CCl4 used, caused liver injury in rats. The rats treated with an overdose of CCl4 developed significant hepatic damage, which was observed through a substantial increase in the concentration of serum parameters. Pretreatment of the rats with *C. sativum* extract at 100 and 200 mg/kg for 15 days before CCl4 administration resulted in a significant protection of CCl4-induced by the elevation of serum marker enzymes. *C. sativum* appears to be effective in reducing the injurious effect of CCl4 observed in the study. This was an indication of stabilization of plasma membrane, as well as repair of hepatic tissue damage, caused by CCl4. The results are in agreement with the commonly accepted view that serum level of transaminase returns to normal with healing of hepatic parenchyma and the regeneration of hepatocytes. Further, the stimulation of hepatic regeneration was known to make the liver more resistant to damage by toxins (Thabrew et al., 1987).

In the present study pretreatment with *C. sativum* showed increased activity of antioxidant enzymes compared to CCl4 treated animals indicating the potentiality of *C. sativum* to act as an antioxidant by preventing the peroxidative damage caused by CCl4. Total Protein is done as a routine test to evaluate the toxicological nature of various chemicals (Nevin and Vijayammal, 2005). The decreased total protein in CCl4 treated groups is due the damage caused to the liver by CCl4. The ability of *C. sativum* to maintain the total protein may be due to the non-toxic antioxidant constituents present in the extract.

Hepatic cells participate in a variety of metabolic activities and contain a host of enzymes. In tissues, Aspartate amino transferase (AST) and Alanine amino transferase (ALT) are found in higher concentrations in cytoplasm and AST in particular also exists in mitochondria. In liver injury, the transport function of the hepatocytes is disturbed, resulting in the leakage of plasma membrane, thereby causing an increased enzyme level in serum, and soluble enzymes like AST also will be similarly released. The elevated activities of AST and ALT in serum are indicative of cellular leakage and loss of functional integrity of cell membranes in liver (Rajesh and Latha, 2004). Administration of CCl4 significantly raised the serum level of enzymes like AST and ALT in rats as observed in our result. Oral administration of *C. sativum* at a dose of 200 mg/kg body weight to rats caused a decrease in the activity of the above enzymes, which may be a consequence of the stabilization of plasma membrane as well as repair of hepatic tissue damage caused by CCl4. This is supported by the view that serum levels of transaminases return to normal with the healing of hepatic parenchyma and regeneration of hepatocytes (Thabrew et al., 1987). SGOT is found in the liver, cardiac muscles, skeletal muscles, pancreas, lungs, kidney, brain, etc., where as SGPT concentration is highest in the liver and therefore, it appears to be more sensitive test for hepatocellular damage than SGOT (Lin et al., 1997).

Leakage of large quantities of enzymes into the blood stream is often associated with massive necrosis of the liver (Shyamal et al., 2006). CCl4 is known to cause marked elevation in serum enzymes (SGOT and SGPT). In the present study, a significant increase in the activities of SGOT and SGPT on exposure to CCl4 was observed, indicating considerable hepatocellular injury. Our results indicated that *C. sativum* (200 mg/kg) administration significantly alleviated the increased serum enzymes induced by CCl4, indicating improvement of the functional status of the liver, which was also supported by the histopathological findings.

The activity of serum alkaline phosphatase was also elevated during CCl4 administration. Alkaline phosphatase is excreted normally via bile by the liver. In liver injury due to hepatotoxin, there is a defective excretion of bile by the liver which is reflected in their increased levels in serum. Hyperbilirubinemia is a very sensitive test to substantiate the functional integrity of the liver and severity of necrosis which increases the binding, conjugation and excretory capacity of hepatocytes that is proportional to the erythrocyte degeneration rate (Singh et al., 1998). Depletion of elevated bilirubin level together with the suppression of activity of ALP in serum of rats treated with *C. sativum*, suggest to stabilize biliary dysfunction of rat liver during chronic injury with CCl4.

Reactive oxygen species (ROS), such as superoxide anions and H2O2, are produced throughout cells during normal aerobic metabolism. The intracellular concentration of ROS is a consequence of both their production and their removal by various antioxidants. A major component of the antioxidant system in mammalian cells consists of three enzymes, namely, superoxide dismutase (SOD), catalase (CAT) and glutathione peroxidase (GPx). These enzymes work in concert to detoxify superoxide anion and H2O2 in cells. Our results indicated that pretreatment of *C. sativum* caused an increase in the activity of antioxidant enzymes. Recent studies on the antioxidant properties of flavonoids from various plant extracts reveal their stimulatory action on antioxidative enzymes (Nagata et al., 1999).

Some flavonoids exert a stimulatory action on transcription and gene expression of certain antioxidant enzymes (Rohrdanz et al., 2002). The antioxidant enzyme system plays an important role in the defence of cells against oxidative insults. The study examined the ameliorating effect of the extracts from *C. sativum*, on oxidative stress induced by CCl4. The levels of glutathione and TBARS approached the normal control in all *C. sativum*-treated animals compared to CCl4. Restoration of TBARS to nearly normal levels by these extracts may be due to an enhancement of antioxidant enzymes, such as superoxide dismutase, catalase, glutathione peroxidase, glutathione reductase and glutathione-S-transferase. In the present study, CCl4 treatment significantly decreased the activity of antioxidant enzymes. Our result is in agreement with several reports.

Most of the hepatotoxic chemicals including CCl4 damaged liver mainly by inducing lipid peroxidation directly or indirectly. In higher animals peroxide radicals are important agents that mediate lipid peroxidation thereby damaging cell membrane, leading to liver injury, atherosclerosis and kidney damage (Recknagel et al., 1989). In the present study, *C. sativum* extract was effective in reducing the production of TBARS. They reported the strongest inhibition of malondialdehyde (MDA), MDA is a major reactive aldehyde that appears during the peroxidation of biological membrane polyunsaturated fatty acid (Vaca et al., 1988). Therefore, the hepatic content of MDA is used as an indicator of liver tissue damage involving a series of chain reactions (Ohkawa et al., 1979).
It has been accepted that lipid peroxidation of hepatocyte membranes is one of the principal causes of CCl4-induced hepatotoxicity, and is mediated by the production of free radical derivatives of CCl4 (Recknagel et al., 1989; Basu, 2003 and Weber et al., 2003). In the present study, a single dose of CCl4 at 1 ml/kg resulted in a significant increase in the hepatic MDA concentration, indicating increased lipid peroxidation caused by administration of CCl4. Highly significant activities of superoxide dismutase and catalase were correlated with the reduction of lipid peroxides. The significant dose-dependent decrease in the hepatic MDA concentration confirms that pretreatment with C. sativum extracts could effectively protect against the hepatic lipid peroxidation induced by CCl4.

The histological observations basically supported the results obtained from serum enzyme assays. The liver of CCl4 intoxicated rats showed massive fatty changes gross nerosis, broad infiltration of lymphocyte and kupffer cells around the central vein and loss of cellular boundaries. The histopathological observations of the liver of rats pretreated with C. sativum and subsequently given CCl4 showed a more or less normal architecture of the liver having reversed to a large extent, the hepatic lesions produced by the toxin, almost comparable to the normal control and silymarin groups. It is suggested that C. sativum acts by its stabilizing effect on the plasma membrane as was reported in case of silymarin. The stimulation of hepatic regeneration makes the liver more resistant to damage by the toxin (Sadasivan et al., 2006). C. sativum inhibited liver lipid peroxidation and resultant tissue degeneration, thus acting as an effective antioxidant.

In conclusion, it may be mentioned that the altered biochemical profiles due to CCl4 exposure is reversed towards normalization by C. sativum extract but the effect was more pronounced with the leaf extract. The contents of the extract not only protect the integrity of plasma membrane but, at the same time increased the regenerative and reparative capacity of the liver. Beneficial effect of the C. sativum extract may be due to the presence of some phytochemical components that have membrane stabilizing effects. These results suggest that the compound present in the plant extract efficiently works on the liver to keep it normally functioning and minimizing cell membrane disturbances.

Conflict of interest statement

The authors declare that there are no conflicts of interest.
